

Bernoulli model with conjugate priors

Case study: Space shuttle Challenger disaster

Georgios P. Karagiannis @ MATH3341/4031 Bayesian statistics III/IV (practical implementation)

Back to the main document

```
rm(list=ls())
```

Aim

Students will become able to:

- produce Monte Carlo approximations of posterior quantities required for Bayesian analysis with the RJAGS R package
- implement Bayesian posterior analysis in R with RJAGS package

Students are not required to learn by heart any of the concepts discussed

Reference list

The material about RJAGS package is not examinable material, but it is provided for the interested student. It contains references that students can follow if they want to further explore the concepts introduced.

New software

- R package `rjags` functions:

```
- jags.model{rjags}

- jags.samples{rjags}
- update{rjags}
```

Application: Challenger O-ring

On January 28, 1986, a routine launch was anticipated for the Challenger space shuttle. Seventy-three seconds into the flight, disaster happened: the shuttle broke apart, killing all seven crew members on board. Here is the video. The Rogers commission concluded that the Challenger accident was caused by gas leak through the 6 O-ring joints of the shuttle. Essentially the presence of distressed O-ring joints was the crucial factor that caused the explosion.

Dalal, Fowlkes and Hoadley (1989) analysed a dataset that contains the presence of distressed O-rings, the temperature in the platform, and the leak check pressure for 23 previous shuttle flights. The data-set is provided below, where in column *Defective.O.rings*, (1) stands for presence of distressed O-rings, and (0) for absence, while the rest columns are self explained.

```
# Load R package for printing
library(knitr)
library(kableExtra)

# load the data
mydata <- read.csv("./challenger_data.csv")
# print data
## (that's a sophisticated command with fancy output, feel free to ignore it)
kable(mydata)%>%
  kable_styling(bootstrap_options = c("striped", "hover"))
```

Here,

- we will use only the observations in variable *Defective.O.rings* (so ignore the temperature and pressure measurements) from 04/12/1981 to 01/12/1986 (23 flights), with purpose to:
 - learn the (limiting relative) frequency of having defective O-rings?
 - predict the outcome in the 24th flight on 1/28/86, given the information from the previous 23 flights considered.
-

The model: Bernoulli model

Let y_i denote the presence of a defective O-ring in the i th flight (0 for absence, and 1 for presence).

Regarding the statistical model, we assume that y_i can be modeled as observations generated independently from a Bernoulli distribution with common parameter p . Here, p denotes the relative frequency of defective O-rings at any flight.

Regarding the prior model, we assign a Beta prior distribution with fixed hyper-parameters $a_0 = 1.0$, $b_0 = 1.0$ on p to account for its uncertainty.

The Bayesian hierarchical model under consideration is:

$$\begin{cases} y_i | p \sim \text{Bernoulli}(p), & \text{for } i = 1, \dots, n \\ p \sim \text{Beta}(a_0, b_0), \end{cases}$$

with hyper-parameter values $a_0 = 1.0$, $b_0 = 1.0$.

Task

Write the RJAGS program implementing the hierarchical model above, in order a sample of size $N = 100000$ from the posterior distribution

$$p^{(j)} \sim \pi(p | y_{1:n}), \quad j = 1, \dots, N.$$

Analysis using the rjags package proceeds in steps:

1. Load the library `rjags`
2. Create an input script, for rjags, containing the Bayesian hierarchical model
3. Create an input list, for jags, containing the data and fixed parameters of the model
 - use `list {base}`
4. Creates an object of class “jags”. To do this you need to read the model file by using the `jags.model{rjags}` function.
 - use `jags.model{rjags}`
5. Generate a posterior sample. To do this you need to extract samples from the model object using the `jags.samples` function.
 - use `update{rjags} ; jags.samples{rjags}`

... your answer

Below try to address the task by creating R chunks, and running them, and adding comments to the document.

step 1

Load the library

```
# Load rjags
library("rjags")
```

step 2

Create an input script, for rjags, containing the Bayesian hierarchical model

```
# Input parameters : n, y, a_0, b_0
# output parameters : p
hierarhicalmodel <- "

model {

  # this is related tot he sampling distribution

  for ( i in 1 : n ) {
    y[ i ] ~ dbern( p )
  }
}
```

```

# this is related to the prior distributions

p ~ dbeta( a_0 , b_0 )

}

"

```

step 3

Create an input list, for jags, containing the data and fixed parameters of the model

```

y_obs <- mydata[ -nrow(mydata) , 4 ] # exclude the last row, and use only the 4th column

y_obs <- as.numeric( y_obs == 1 )    # make it numeric

n_obs <- length( y_obs )

a_0 <- 1.0

b_0 <- 1.0

data.bayes <- list(y = y_obs,
                  n = n_obs,
                  a_0 = a_0,
                  b_0 = b_0)

```

step 4

Create an input list, for jags, containing the data and fixed parameters of the model

```

model.smpl <- jags.model( file = textConnection(hierarhicalmodel),
                        data = data.bayes)

```

For further reading:

Alternatively we could have used the routine `coda.samples{rjags}` returning the same information but with an object of type `mcmc.list` that can be analysed by the tools provided in the R packages `coda` and `boa`. We do not discuss about these packages as they are not in stable release yet, and they may contain bugs. Pls keep an eye on them.

step 5

Initialize the sampler with $N_{\text{adapt}} = 1000$ iterations.

- This is a warming-up procedure (used as a black-box), where the sampler is automatically tuned and calibrated before it starts generating your samples.
- Regarding $N_{\text{adapt}} = 1000$, the larger the better.

```

adapt( object = model.smpl,
       n.iter = 1000 )

```

```
## [1] TRUE
```

step 6

Generate a posterior sample of size $N = 10000$.

Use

- `jags.samples{rjags}`

We need to pay attention on two flags:

- the `n.iter`: the total size of the total sample sequence.
- the `variable.names`: it specifies the names of the random variables correspondign to the posterior samples I am interested in generating

```
N = 10000      # the size of the sample we ll gonna get
output = jags.samples( model= model.smpl,      # the model
                       variable.names= c("p"), # names of variables to be sampled
                       n.iter = N             # size of sample
)
```

Check the names of the variables sampled

- use `names {base}`

```
names(output)
```

```
## [1] "p"
```

Check the dimensions of each of the variables sampled

- use `dim {base}`

```
dim( output$p )
```

```
##          iteration      chain
##          1      10000         1
```

```
# the first dimension is the numbers of columns of the variable
# the second dimention is the size of the sample drawn
# the thirs dimention is the number of the sub-samples drawn (in our case it is just 1)
```

Copy the sample of each variable in a vector with a more friendly name...

```
pr.smpl <-output$p
```

Task

Extract the sample drawn from the posterior distribution

$$p^{(j)} \sim \pi(p|y_{1:n}) \quad j = 1, \dots, N$$

and print the trace plot of the sample.

Use functions:

- `plot {graphics}`.

Snapshot from Tem 2:

- A good quality sample for the purposes of Monte Carlo integration is the one whose trace plot looks completely uncorelated.
 - e.g. like the independence assumption in the siple linear regression in SC2.
- To improve the quality of the sample, you can go back to the sampling stem and play with the flaq values of `n.iter` and `thin` in `jags.samples{rjags}`.

... your answer

Below try to address the task by creating R chunks, and running them, and adding comments to the document.

```
# write your R code
```

Task

- Compute and plot the MC approximation for the posterior distribution cumulative function (CDF) of p , by computing the empirical CDF as

$$\begin{aligned} F_{\pi}(p \leq c | y_{1:n}) &= E_{\pi}(1(p \leq c) | y_{1:n}) \\ &\approx \frac{1}{N} \sum_{i=1}^N 1(p^{(i)} \leq c) \end{aligned}$$

for $c \in (0, 1)$

- Compute and plot the exact posterior CDF of p , which is the CDF of the distribution

$$p | y_{1:n} \sim \text{Beta}(a_n, b_n)$$

where

$$\begin{aligned} a_n &= a_0 + n\bar{y} \\ b_n &= b_0 + n - n\bar{y}. \end{aligned}$$

by printing them on the same plot.

Use functions:

- `lines {graphics}`

... your answer

Below try to address the task by creating R chunks, and running them, and adding comments to the document.

```
# write your R code
```

Task

- Compute and plot the MC approximation for the posterior distribution density of $p | y_{1:n}$ as a histogram

$$\pi(p | y_{1:n}) \approx \frac{1}{2\epsilon} \frac{1}{N} \sum_{j=1}^N 1\left(p^{(j)} \in (p - \epsilon, p + \epsilon]\right) \text{ for small } \epsilon$$

for $p \in (0, 1)$,

- use the function `hist {graphics}` provided from R, instead... no need for you to choose the optimal ϵ value.

- Compute and plot the exact the posterior distribution density of $p|y_{1:n}$ which is the PDF of

$$p|y_{1:n} \sim \text{Beta}(a_n, b_n)$$

where

$$\begin{aligned} a_n &= a_0 + n\bar{y} \\ b_n &= b_0 + n - n\bar{y}. \end{aligned}$$

Use functions:

- `hist {graphics}`

... your answer

Below try to address the task by creating R chunks, and running them, and adding comments to the document.

write your R code

Task

- Compute the MC approximate of the posterior probability that the frequency parameter p is greater than or equal to 0.5 as

$$\Pr_{\pi}(p \geq 0.5|y_{1:n}) = 1 - \Pr_{\pi}(p < 0.5|y_{1:n}) \quad (1)$$

$$= 1 - \mathbb{E}_{\pi}(1(p < 0.5)|y_{1:n}) \quad (2)$$

$$\approx \frac{1}{N} \sum_{i=1}^N (1(p^{(i)} < 0.5)) \quad (3)$$

- Compute its exact value of as

$$\Pr_{\pi}(p \geq 0.5|y_{1:n}) = 1 - \Pr_{\pi}(p < 0.5|y_{1:n}) \quad (4)$$

$$= 1 - \Pr_{\text{Beta}(a_n, b_n)}(p < 0.5|y_{1:n}) \quad (5)$$

$$= 1 - \int_{-\infty}^{0.5} \text{Beta}(p|a_n, b_n) dp \quad (6)$$

where

$$\begin{aligned} a_n &= a_0 + n\bar{y} \\ b_n &= b_0 + n - n\bar{y} \end{aligned}$$

... your answer

Below try to address the task by creating R chunks, and running them, and adding comments to the document.

```
# write your R code
```

Task

- compute the MC approximate of the 95% posterior equal tail credible interval of the frequency parameter p is

$$[Q_{0.025}(p|y_{1:n}), Q_{0.975}(p|y_{1:n})]$$

where $Q_{\alpha}(p|y_{1:n})$ is the α -th quantile of the posterior distribution of p

- compute the exact 95% posterior equal tail credible interval of the frequency parameter p is

$$[Q_{0.025}(p|y_{1:n}), Q_{0.975}(p|y_{1:n})]$$

where $Q_{\alpha}(p|y_{1:n})$ is the α -th quantile of the posterior distribution of p which is

$$p \sim \text{Beta}(a_n, b_n)$$

where

$$a_n = a_0 + n\bar{y}$$

$$b_n = b_0 + n - n\bar{y}$$

Use:

- `quantile{stats}`
- `qbeta{stats}`

... your answer

Below try to address the task by creating R chunks, and running them, and adding comments to the document.

```
# write your R code
```

Task

- Compute the MC approximate of the posterior expected value of p , $E_{\pi}(p|y_{1:n})$, as

$$E_{\pi}(p|y_{1:n}) \approx \frac{1}{N} \sum_{i=1}^N p^{(i)}$$

- Compute exact value of $E(p|y_{1:n})$ which is

$$E_{\pi}(p|y_{1:n}) = \frac{a_n}{a_n + b_n}$$

where

$$a_n = a_0 + n\bar{y}$$

$$b_n = b_0 + n - n\bar{y}$$

... your answer

Below try to address the task by creating R chunks, and running them, and adding comments to the document.

```
# write your R code
```

Task

- Compute the MC approximate of the posterior expected value of the odds parameter $\theta = \frac{p}{1-p}$ which is denoted as $E_{\pi}(\theta|y_{1:n})$.

$$E_{\pi}(\theta|y_{1:n}) = E_{\pi}\left(\frac{p}{1-p}|y_{1:n}\right) \approx \frac{1}{N} \sum_{i=1}^N \frac{p^{(i)}}{1-p^{(i)}}$$

- Compute the MC approximation of $E_{\pi}(\theta|y_{1:n})$ with its exact value which is

$$E_{\pi}(\theta|y_{1:n}) = E_{\pi}\left(\frac{p}{1-p}|y_{1:n}\right) = \frac{a_n}{b_n - 1}$$

where

$$\begin{aligned} a_n &= a_0 + n\bar{y} \\ b_n &= b_0 + n - n\bar{y} \end{aligned}$$

... your answer

Below try to address the task by creating R chunks, and running them, and adding comments to the document.

```
# write your R code
```

Task

- Compute the MC approximation of the predictive distribution mass function of $y_{n+1}|y_{1:n}$, as

$$\begin{aligned}
 f_{\pi}(y_{n+1} = c|y_{1:n}) &= \int_0^1 f(y_{n+1} = c|p)\pi(p|y_{1:n})dp, \quad c \in \{0, 1\} \\
 &= \int_0^1 p^c(1-p)^{1-c}\pi(p|y_{1:n})dp, \quad c \in \{0, 1\} \\
 &= \begin{cases} \int_0^1 (1-p)\pi(p|y_{1:n})dp & , c = 0 \\ \int_0^1 p\pi(p|y_{1:n})dp & , c = 1 \end{cases} \\
 &= \begin{cases} 1 - E(p|y_{1:n}) & , c = 0 \\ E(p|y_{1:n}) & , c = 1 \end{cases} \\
 &\approx \begin{cases} 1 - \frac{1}{N} \sum_{j=1}^N p^{(j)} & , c = 0 \\ \frac{1}{N} \sum_{j=1}^N p^{(j)} & , c = 1 \end{cases}
 \end{aligned}$$

by using a barplot.

- Compute the exact predictive distribution mass function of $y_{n+1}|y_{1:n}$, as

$$\begin{aligned}
 f(y_{n+1} = c|y_{1:n}) &= \frac{B(a_n + c, b_n + 1 - c)}{B(a_n, b_n)} 1(c \in \{0, 1\}) \\
 &= \begin{cases} \frac{B(a_n, b_n + 1)}{B(a_n, b_n)} & , c = 0 \\ \frac{B(a_n + 1, b_n)}{B(a_n, b_n)} & , c = 1 \end{cases}
 \end{aligned}$$

where

$$\begin{aligned}
 a_n &= a_0 + n\bar{y} \\
 b_n &= b_0 + n - n\bar{y}
 \end{aligned}$$

by using a barplot.

Use functions:

- `barplot {graphics}`,
